

MULTI-SECTOR ANTENNA APPARATUS

FEDERALLY SPONSORED RESEARCH OR DEVELOPMENT:

5 Not Applicable.

RELATED APPLICATIONS:

10 This Application claims priority from Provisional Applications: Serial No. 60/461,003,
Attorney Docket No. OFE 1841P, filed: April 7, 2003; Serial No. 60/535,001, Attorney Docket
No. OFE 1849P, filed: January 7, 2004.

BACKGROUND OF THE INVENTION:

15 Mobile and wireless communications are exhibiting explosive growth—evident by the
continued growth of cellular systems, 802.11-based data communications and the increased
demand for broadband-based communications. The Internet's success results from IP
architecture's robustness, flexibility, and ability to scale over multiple wired networks. The
Internet is in the process of expanding to wireless and ad-hoc networking environments. Wireless
environments will be able to support mobility--a feature that is desired by the highly dynamic
user community. One of the main constraints limiting the spread of wireless networking is that
20 systems supporting mobile communications have considerably less transmission capacity than
wire-based networks. This invention introduces a novel wireless communications and antenna
design in order to significantly increase the number of users that systems can support, and
increase wireless networks' aggregate transmission capacities.

25 The field of the invention is antenna system design for wireless data networks, by dividing
three-dimensional space into multiple regions or sectors, wherein the antenna system design
primarily occupies one sector of the space. Consequently, it is possible to use the same frequency
at the same time in non-interfering parts of three-dimensional space. A similar concept of
sectoring has been used in cellular-based systems, however this invention uses a different
approach by which the sectoring, the specific antenna structure and the channel selection process
30 is done dynamically (packet-by-packet) both in an access point and a mobile device. Energy can

then be channeled to the antenna module, which will maximize communication efficiency, and reduce power requirements that are important for mobile users who don't have fixed power sources.

The field of the invention further relates to smart antenna design, e.g.: phased array antennas, SDMA (space division multiple access) antennas, spatial processing antennas, digital beam-forming antennas, ceramic antennas, strip antennas, adaptive antenna systems, flat panel antennas, etc. Smart antenna systems can be characterized as either switched-beam or beam-forming systems, with the following distinctions regarding the choices in transmission strategy:

- Switched-beam antenna systems form multiple fixed-beams with heightened sensitivity in predefined directions. These antenna systems detect signal strength, choose from one of several predetermined fixed-beams, and switch from one beam to another as the mobile moves throughout the sector. Instead of shaping the directional antenna pattern with the metallic properties and physical design of a single element (e.g., a sectorized antenna), switched-beam systems combine the outputs of multiple antennas in such a way as to form finely sectorized (directional) beams with more spatial selectivity than can be achieved with conventional, single-element approaches.
- Beam-forming antennas have an infinite number of patterns that are adjusted in real-time. Using a variety of signal-processing algorithms, the adaptive system takes advantage of its ability to effectively locate and track various types of signals to dynamically minimize interference and maximize intended signal reception.

Both switched-beam antennas and beam-forming antennas attempt to increase gain and minimize interfering signals according to the location of the individual user. The system and antenna designs in this invention are aimed at increasing gain, reducing power requirements and minimizing interfering signals with respect to a large number of mobile users who are concurrently and continuously tracking and communicating with their respective access points.

In addition to these techniques, smart antennas provide a new method of multiple access to the users, which is known as space division multiple access (SDMA). The SDMA scheme, sometimes referred to as space diversity, uses smart antennas to provide control of space by providing virtual channels in an angle domain. With the use of this approach, simultaneous calls in various different cells can be established at the same carrier frequency. SDMA complements

CDMA (code division multiple access) and TDMA (time division multiple access) by increasing the number of users that can access an existing wireless phone or data system by exploiting the spatial characteristics of the channel itself through highly developed implementation of an intelligent antenna system's capabilities for receiving and transmitting.

5 SDMA antenna systems are used on board various satellite systems. SDMA permits multiple signals of different polarization to simultaneously access the same satellite transponder. Users share a common frequency, but are separated by spatial processing. With SDMA, satellites may achieve signal separation by using beams with horizontal, vertical or circular polarization. This technique allows multiple beams to cover the same earth surface areas. Additionally, the
10 satellite could achieve spatial separation by using separate antennas or a single antenna with multiple beams.

PRIOR ART:

The following examines related patents to this current patent application. The invention describes in [*"Direction-agile antenna system for wireless communications,"* United States Patent 6,486,832, Abramov, et al., November 26, 2002] discloses an antenna steered by an electro-mechanical device in the direction that ensures maximal quality of the incoming signal.

The invention described in [*"AI antenna driving device and method for controlling the same,"* United States Patent 6,278,405, Ha , et al., August 21, 2001] tries to overcome the limitations of a fixed antenna by using a mechanical antenna steering mechanism to improve reception and transmission.

The invention described in [*"Multiple antenna cellular network,"* United States Patent 6,070,071, Chavez , et al., May 30, 2000; *"Multiple antenna cellular network,"* United States Patent 6,078,823, Chavez , et al., June 20, 2000] concentrates on cellular communication networks. It proposes a multiple antenna cellular network communicates with a mobile station over a plurality of antennas. The antennas are arranged in a plurality of positions to customize a cell or cells. A transceiver is coupled to the antennas and configured to receive inbound information from the mobile station and transmit outbound information to the mobile station. A processor is coupled to the transceiver and configured to decode the inbound information and to encode the outbound information to communicate with the mobile station. In another embodiment, the antennas are similarly deployed to create a cell or cells. The transmit signal power is continuously modified to improve quality and to move the nulls so that a fixed location user can receive a high quality signal. A cell can be served by multiple antennas overcoming the limitations imposed by conventional cellular systems. Communications are supported through

walls, ceilings, floors and buildings to reduce interference, improve performance and improve quality of service.

Exemplary embodiments are provided for use with the Global Systems for Mobile Communication (GSM) protocol and can be applied to other digital technologies. The invention described in [“Switched directional antenna for automotive radio receivers,” United States Patent 6,449,469, Miyahara September 10, 2002] proposes a method for improving communications from and to a moving vehicle. It relates, in general, to a mobile radio receiver with reduced distortion and reduced signal fading, and more specifically, to a switched directional antenna utilizing predetermined antenna patterns aligned with the front, back, left and right sides of a mobile vehicle. A primary source of noise and distortion in radio receivers is derived from multi-path interference. This is a localized effect resulting from interaction between separate signals from a transmitter, which traverse different paths (e.g., via reflections) to reach a receiving antenna. Because of the superposition of several signals (e.g., echoes and direct waves), the signal strength of the received signal changes drastically and may fall below the noise floor. Based upon the differences in path lengths of each received wave, the multi-path distortion or fading may include short—time delayed multi-path interference and/or long—time delayed multi-path interference signals.

A well-known means for reducing multi-path distortion is through use of space-diversity antennas in a radio receiver system. By switching between antenna signals from spaced apart antennas. Specific multi-path events can be avoided if the antenna spacing is enough to insure that both antennas will not experience the same multi-path event at the same time. By using the different antennas placed on the vehicle it is possible to reduce the multi-path effect and improve the communication system performance.

The invention described in [“Multi-sector pivotal antenna system and Method,” United States Patent 5,969,689, Martek, et al., October 19, 1999] proposes using an omni-directional coverage multi-beam antenna composed of facets or antenna modules that comprise a regular polygon of n sides inscribed in a circle of radius r which defines an adjustable composite conical surface. The antenna modules are independent antenna arrays creating an independent beam. One advantage of such a system is that the radiated wave front associated with such antenna modules is always substantially broadside to the array resulting in limited scan loss effects. Furthermore;

the independence of the disclosed antenna modules is important as it allows each module's beam to be either electrically or mechanically steered to affect elevation or directional beam control. The individual antenna modules can be steered to be directed within the area covered by a module to optimize communications capability.

5

SUMMARY OF THE INVENTION:

10 The present invention relates to the concept of sectoring in cellular phone systems. Existing wireless networking systems are based upon assigning a channel (frequency, time or code) to a mobile user. The channel remains assigned to his mobile device until a significant reduction in his signal to noise ratio is detected, at which point a network control system attempts to find an available channel which can serve him and assigns the user to that channel. This process is repeated throughout the session.

15 The present invention is not restricted to cellular communication systems—an access point and/or a mobile unit can have multiple directional antennas, each directed to a different sector of three-dimensional space, and the antenna selection is done packet-by-packet. This allows for a packet-by-packet decision and reduces the delay from received signal to transmission and improves the system response time.

The approach presented in this invention is distinguished in several ways:

- 20 1. Antenna design: the use of several antennas each pointing to a different sector (direction). By listening to the incoming signals, a control system detects which antenna receives the best signal to noise ratio from a mobile user and directs the next packet for that user to be sent through that antenna sector.
2. The detection and decision making is done packet-by-packet – taking advantage of the best available current information.
- 25 3. Gains are achieved by increasing the range (distance) that a mobile user and an access point can communicate by directing the transmission power to a single sector. By directing the transmission energy in a single direction, it is possible to reduce the interference between different devices and support an increased number of mobile users that can be served by a single access point.

4. The energy required for effective communication is reduced and will decrease the battery drainage from a mobile user device, thus extending the amount of time between battery charges when users are closer to the access point.
5. The design allows a device to simultaneously communicate with several access points – increasing the transfer rate from and to the mobile device. Additionally, a mobile device serves as a relay node between access points and mobile devices, and between mobile-to-mobile devices.

The basic concept is that a device (mobile or static), is equipped with multiple directional antennas (modules) which divide space into sectors. The signals arriving through each sector are continuously analyzed; identifying which sector provides the best incoming signal from each access point or other mobile units. When the device/access point has to transmit a packet to another device it selects the antenna sector that had the best reception from the receiving device and directs the transmission power to that sector. This process is repeated until the communication session is terminated or until no further communication is possible between the two parties.

The present invention claims multiple designs of previously discussed directional antennas; systems to receive signals, store and analyze them; a general architecture to select the transmission antenna module and methods to transfer the transmitted packet to the appropriate antenna module. More specifically, this invention is related to a wireless system for transmitting and receiving a plurality of data packets. The wireless system comprises a plurality of directional antenna sectors, at least one receiving controller and at least one transmitting controller. Each directional antenna sector, when coupled to a selected one of the transmitting controllers, transmits an electromagnetic signal in a defined region in three-dimensional space. A selected one of the receiving controllers is selectively coupled to at least one of the directional antenna sectors in order to measure the received electromagnetic signal characteristics. A selected one of the receiving controllers selects at least one of the directional antenna sectors within a first predefined time interval prior to the transmission of at least one data packet responsive to the received electromagnetic signal characteristics. A selected one of the transmitting controller is selectively coupled to at least one of the directional antenna sectors in order to transmit at least one data packet via the directional antenna sectors selected by the receiving controller.

Methods and systems for packet-by-packet directional mobile wireless transmission utilizing plurality of directional antenna sectors are claimed, such that the transmission of each packet is performed by at least one selected antenna sector. The direction of transmission is selected responsive to the direction from which the best electromagnetic signal reception was received. For each plurality of data packets, the transmission direction is selected again. Switching logic couples the out-going transmission signal to selected ones from the plurality of the antennas responsive to the motion of the mobile user. The antenna design in this invention is aimed at increasing the gain and minimizing the interfering signals with respect to large numbers of mobile users who are concurrently and continuously tracking and communicating with their access points, and consequently, increasing the bit rate of each transmission and the aggregate capacity of the wireless system.

BRIEF DESCRIPTION OF THE DRAWINGS:

Fig. 1 is a general description of a system comprised of a base station (BS) and a plurality of mobile devices (MDs). The MDs are connected to BS via a wireless link by using an antenna system (AS). The AS is comprised of a plurality of antenna sectors.

Fig. 2 is a deployment scenario utilizing the proposed system in a residential neighborhood. In this deployment scenario, the neighborhood base station is connected by means of wireless links to residence antennas. The residence antenna is connected to access point routers via wireless or wired links. Various mobile and fixed devices are connected to the access point routers by means of wireless or wired links.

Fig. 3 is a geometrical definition of an antenna sector electromagnetic radiation in three-dimensional (3-D) space.

Fig. 4 is a functional description of the mobile device (MD) and the antenna system (AS) that is comprised of N antenna sectors coupled to an antenna control unit by means of switches, transmit/receive coupling (TRC), TRF (transmit radio frequency), RRF (receive radio frequency), receivers and transmitters. Specifically, in this functional description, the TRFs are located to couple the transmitters to the T -to- N switch and the RRFs are located to couple the receivers to the N -to- R switch.

Fig. 5 is a functional description of the mobile device (MD) and the antenna system (AS) that is comprised of N antenna sectors that are coupled to an antenna control unit by means of switches, transmit/receive coupling (TRC), TRF (transmit radio frequency), RRF (receive radio frequency), receivers and transmitters. Specifically, in this functional description, the TRFs are located to couple the T -to- N switch to the TRCs and the RRFs are located to couple the TRCs to the N -to- R switch.

Fig. 30 is a functional description of an antenna system utilizing four flat panel directional antenna sectors that are attached to an antenna structure **3000** with arms. The antenna system contains an antenna control system **2930** that is connected to a computing device **2940** via a communications channel **2950**.

20 **Fig. 31** is a schematic description of a vertical slice of cylindrical structure such that six such vertical slices with hexagonal arrangement are needed for covering 360°. This vertically stackable example provides for quadruple spatial vertical coverage.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT:

25 While this invention is susceptible of embodiment in many different forms, there are shown in the drawings, and will be described herein in detail, specific embodiments thereof with the understanding that the present disclosure is to be considered an exemplification of the principles of the invention and is not intended to limit the invention to the specific embodiments illustrated.

The present invention relates to a method and system for increasing transmission capacity of wireless networks.

General Description

The following are some acronyms used in this preferred embodiment description:

- TRC – Transmit/Receive (Directional) Coupling
- TRF/PA – Transmit RF (Radio Frequency) / Power Amplifier
- RRF/LNA – Receive RF (Radio Frequency) / Low Noise Amplifier
- MOD – Modulator
- DEMOD – Demodulator
- WL – wireless

Fig. 1 and **Fig. 2** are general descriptions of the present invention. As shown in **Fig. 1**, the base station (BS) **110** communicates by means of wireless or radio channel **120** with a plurality of wireless devices (WDs) **130** via a plurality of antenna systems (AS) **150**. The AS **150** is connected to its respective WD **130** via a link **140**—at at least a wireless link or a wired link. Each antenna system **150** consists of a plurality of antenna sectors **160**.

An antenna is defined as being an efficient radiator of electromagnetic energy by converting a fluctuated voltage into the electromagnetic wave during transmission, and it converts the electromagnetic wave into voltage during reception. Antennas have five basic properties: bandwidth, directivity, power gain, polarization, and radiation pattern.

The main antenna property that is used in this invention is directivity. Each antenna sector **160** is radiating electromagnetic energy in a predefined direction covering a predefined region of three-dimensional space, as show in **Fig. 3**. Consequently, there is a plurality of antenna sectors **160** enable radiating electromagnetic energy covering parts or the whole three-dimensional space.

The base station **110** in **Fig. 1** consists of at least one antenna that radiates electromagnetic energy in a predefined direction covering a predefined sector of three-dimensional space. A specific case of the base station **110** antenna is an omni antenna that transmits in all directions. In an alternate configuration, the base-station **110** has three antenna sectors covering a predefined sector of three-dimensional space, wherein the predefined sector of three-dimensional space by combining the coverage of the three antenna sectors.

The antenna system **150** selectively activates the antenna sectors **160**, in order to have the best the quality of transmission and reception between the wireless device **130** and the base station **110**. The wireless device **130** is a mobile device, carried by a person or by other means. In order to improve the wireless system performance, the mobile device will continuously monitor, and change as needed, the antenna sector **160** used for transmission and reception of data packets with the base station **110**.

The antenna system **150** in this invention is a novel type of a sectorized (with multiple sectors) antenna system that selectively cover parts of the three-dimensional space by selectively activating fixed antenna beams with heightened sensitivity in particular directions. The antenna system **150** detects signal strength; chooses from one of several predetermined, fixed antenna sectors **160**, and switches from one antenna sector to another as the mobile user moves or as a result of changing wireless transmission conditions. The antenna system **150** is shaping the directional antenna pattern with the metallic properties and physical design of a single element. The antenna system **150** will increase gain according to the location of the wireless device **130** with respect to the base station **110**, while simultaneously identifying and tracking the base station **110**, and minimizing interfering signals from other wireless devices **130** and other base stations **110**.

Fig. 2 is another general description of the present invention. As shown in **Fig. 2**, there is a neighborhood (e.g., hot spot) base station (BS) **110** that is communicating by means of wireless or radio channel **120** with a plurality of residence antenna systems **150** each with a plurality of antenna sectors **160**. The residence antenna systems **150** are connected to a plurality of access point routers **230** via a plurality of links **220**— at least wireless links or a wired links. The access point routers **230** are functionally equivalent to the base station **110** (**Fig. 1**). The access point routers **230** are connected to various mobile devices **240** via a shared wireless link, wherein the shared wireless link is at least one of: IEEE 802.11, IEEE 802.15, IEEE 802.16, 3G and 4G.

Specifically, the wireless connection between the neighborhood base station **110** and the plurality of residence antennas **150/160** can be used for fixed wireless, e.g., LMDS (Local Multipoint Distribution Service) - IEEE 802.16. The unique directional properties enable the residence antenna **150/160** to adapt to changing wireless transmission conditions, e.g., solving

the need to manually adjust and redirect the fixed antenna due to the changing quality of multi-path wireless transmissions.

The access point router **230** is also equipped with an antenna system **150** with a plurality of antenna sectors **160** (see **Fig. 1**), and consequently, can adapt to changing wireless transmission conditions, e.g., solving the need to manually adjust and redirect the fixed antenna of the access point router **230** due to the changing quality of multi-path wireless transmissions.

The various mobile devices **240** in **Fig. 2** are connected to the neighborhood base station **110** in at least one of the following ways:

- Via the access point router **230** to the neighborhood base station **110**,
- Via the access point router **230** and the residence antenna **150/160** to the neighborhood base station **110**,
- Via the residence antenna **150/160** to the neighborhood base station **110**, and
- Directly communicating with the neighborhood base station **110**.

The various mobile devices **240** in **Fig. 2** are equipped with the antenna system **150** with a plurality of antenna sectors **160**. The various mobile devices **240** are at least one of: laptop computer, personal digital assistant, cellular phone, 2.5G cellular phone, 3G wireless device, 4G wireless device, consumer electronic games, multimedia wireless devices, videoconferencing system, wireless packet audio system, wireless packet video system, electronic book and electronic paper.

Fig. 3 is a general possible description and definition of a directional sectorized antenna **160**. Such an antenna radiates or receives electromagnetic waves more effectively in some directions rather than others. Directivity of an antenna is defined as the theoretical characteristic of an antenna to concentrate power in only one direction, whether transmitting or receiving. Gain or antenna gain is the practical value of the directivity of an antenna. It takes into account the efficiency of the complete structure. The antenna power gain is defined as the ratio of the antenna's maximum radiation intensity in a certain direction to the maximum radiation intensity of a reference antenna (dipole, isotropic antenna) with identical power applied to both. Relative antenna power gain is defined as the ratio of the average radiation intensity of the test antenna to the average radiation of a reference antenna with all other conditions remaining equal.

The direction of a directional antenna is often defined having (1) azimuth-horizontal direction expressed as the angular distance between the direction of a fixed point (as the observer's heading) and the direction of the object, and (2) elevation--vertical direction expressed as the angular distance between the direction of a fixed point (as the observer's heading) and the vertical direction of the object.

In **Fig. 3** the azimuth is defined by the "Phi" **311** angle and the elevation is defined the "Theta" **312** angle. The transmit region **320** of a directional antenna is defined using radian (rad.): A unit of plane angle measure is equal to the angle subtended at the center of a circle by an arc equal in length to the radius of the circle. Radian is the Standard International unit of plane angular measure. There are two "pi", or approximately 6.28318, radians in a complete circle. Thus, one radian is about 57.296 angular degrees. The term radian arises from the fact that the length of a circular arc, corresponding to an angle of one radian, is equal to the radius of the arc. This is shown in the illustration. Point *P* represents the center of the circle. The angle *q*, representing one radian, is such that the length of the subtended circular arc is equal to the radius, *r*, of the circle. The radian is used by mathematicians, physicists and engineers. It arises in natural phenomena and in equations which, unlike the angular degree, were invented for human convenience.

As shown in **Fig. 3** the transmit region **320** is covered by a directional or sectorized antenna **160** and can have a rectangular shape or circular shape. In case of a rectangular region for receiving and transmitting **320** it can be defined by azimuth and elevation with radians. In case of a circular region for receiving and transmitting **320** it can be defined using only one measure with radians.

As shown in **Fig. 1**, **Fig. 4** and **Fig. 5**, the present invention is a system for transmitting a plurality of data packets. The system comprises a wireless device, a plurality of antenna sectors, a receiving controller and a transmitting controller. The receiving controller is selectively coupled to at least one of the antenna sectors in order to measure their received electromagnetic signal characteristics. The receiving controller selects at least one of the antenna sectors within a first predefined time interval prior to the transmission of at least one data packet responsive to their received electromagnetic signal characteristics. The transmitting controller is selectively coupled

to at least one of the antenna sectors in order to transmit at least one data packet via the antenna sectors selected by the receiving controller.

As shown in **Fig. 2**, the wireless device is part of at least one of the following: laptop computer, personal computer, personal digital assistant, cellular phone, 2.5G cellular phone, 3G device, 4G device, consumer electronic games, multimedia devices, videoconferencing system, wireless packet audio system, wireless packet video system, electronic book, home entertainment system, electronic paper, GPS (global positioning system) receiver, automotive, boats, ships, airplanes, trains, satellites, hand-held devices, base stations, wireless access points, access routers, electronic scanners, UAV (unmanned aerial vehicle), and packet switch.

As shown in **Fig. 2**, the wireless device is mounted on at least one of: automotive, boats, ships, airplanes, trains, satellites, hand-held devices, laptop computers, base stations, access routers, packet switch outputs.

As shown in **Fig. 3**, selected ones of the antenna sectors are directional antennas, which transmit electromagnetic signals in defined directions covering predefined regions or parts of a three-dimensional space. More specifically, each directional antenna sector transmits in a direction defined using circular three-dimensional coordinates Phi and Theta; wherein each directional antenna transmission covers a respective defined region in three-dimensional space at a respective defined distance in the direction defined with Phi and Theta in circular three-dimensional coordinates. The respective defined region of the transmissions emitted by the directional antennas overlaps a defined part of the three-dimensional space.

802.11 MAC Layer and Collision Avoidance in 802.11:

One of the preferred embodiments of the present invention involves the media access control (MAC) of 802.11 wireless local area network (LAN) standard. The Media Access Control layer specification for 802.11 has similarities to the 802.3 Ethernet wired line standard. The protocol for 802.11 uses a protocol scheme known as carrier-sense, multiple-access, collision avoidance (CSMA/CA). This protocol avoids collisions instead of detecting a collision like the algorithm used in 802.3. It is difficult to detect collisions in an RF transmission network, and it is for this reason that collision avoidance is used. The MAC layer operates together with the physical layer by sampling the transmitted energy over the medium transmitting data. The physical layer uses a clear channel assessment (CCA) algorithm to determine if the channel is

clear. This is accomplished by measuring the RF energy at the antenna and determining the strength of the received signal. This measured signal is commonly known as RSSI (Received Signal Strength Indicator). If the received signal strength is below a specified threshold the channel is declared clear and the MAC layer is given the clear channel status for data transmission. If the RF energy is above the threshold, data transmissions are deferred in accordance with the protocol rules. The standard provides another option for CCA that can be alone or with the RSSI measurement.

Carrier sense can be used to determine if a channel is available. This technique is more selective sense, since it verifies that the signal is the same carrier type as 802.11 transmitters. The best method to use depends upon the levels of interference in the operating environment. The CSMA/CA protocol allows for options that can minimize collisions by using request to send (RTS), clear-to-send (CTS), data and acknowledge (ACK) transmission frames, in a sequential fashion. Communications are established when one of the wireless nodes sends a short message RTS frame. The RTS frame includes the destination and the length of message. The message duration is known as the network allocation vector (NAV). The NAV alerts all others in the medium, to back off for the duration of the transmission.

The receiving station issues a CTS frame, which echoes the sender's address and the NAV. If the CTS frame is not received, it is assumed that a collision occurred and the RTS process restarts. After the data frame is received, an ACK frame is sent back verifying a successful data transmission.

A common limitation with wireless LAN systems is the "hidden node" problem. This can disrupt 40% or more of the communications in a highly loaded LAN environment. It occurs when there is a station in a service set that cannot detect the transmission of another station; thus, cannot detect that the media is busy. As an example, given stations **A**, **B**, and **C** stations: **A** and **C** can communicate; likewise, **B** and **C** can communicate. However, an obstruction prevents station **B** from directly receiving station **A**; thus, **B** cannot determine when the channel is busy. Therefore, both stations **A** and **B** could try to transmit at the same time to station **C**. The use of RTS, CTS, Data and ACK sequences helps to prevent the disruptions caused by this problem.

IEEE 802.11a devices use a different radio technology from 802.11b and operate in the 5 GHz bands. IEEE 802.11a therefore is a supplement to the basic IEEE 802.11 standard. Although

the IEEE 802.11a standard operates in a different unlicensed radio band, it shares the same proven Medium Access Controller (MAC) protocol as Wi-Fi. In more technical terms, IEEE 802.11a standardizes a different physical layer (PHY). Since products conforming to the IEEE 802.11a standard will operate in different radio bands, they will not be interoperable with Wi-Fi radios, which follow the 802.11b-recommendation.

IEEE 802.11b contains some further definitions of the physical layer, and provides for interoperability of Wi-Fi WLAN products. Wi-Fi products operate in the worldwide 2.4 GHz Industry, Science and Medicine (ISM) band.

IEEE 802.11g uses OFDM (Orthogonal Frequency Division Multiplexing) which is a compulsory part of IEEE 802.11g and provides for transmission speeds up to 54 Mbit/sec. It would be compatible with WiFi. It also supports CCK (Complementary Code Keying) in order to be compatible with existing radio units that adhere to IEEE 802.11b. The CCK transmission mode, also used by WiFi, uses one single carrier, while OFDM is a new technique, just entering the WLAN-market. It can be used at both 2.4 and 5 GHz carrier frequencies.

Description of the Wireless Network Adapters in the Current Invention:

Four wireless network adapters are described:

- In **Fig. 4** with N antenna sectors **450**, R receivers **431**, and RRF/LNA **432** (Receive RF (Radio Frequency) / Low Noise Amplifier) between the R receivers **431** and the N -to- R switch **433**. Specific operation details are in **Fig. 11**, **Fig. 12**, **Fig. 13** and **Fig. 14**.
- In **Fig. 5** with N antenna sectors **450**, R receivers **431**, and RRF/LNA **432** (Receive RF (Radio Frequency) / Low Noise Amplifier) between the N antenna sectors **450** and the N -to- R switch **433**. Specific operation details are in **Fig. 11**, **Fig. 12**, **Fig. 13** and **Fig. 14**.
- In **Fig. 7** with two moveable antennas **750**. With specific operation details in **Fig. 8**, **Fig. 15** and **Fig. 16**.
- In **Fig. 9** and **Fig. 10** with array antennas. With specific operation details in **Fig. 17** and **Fig. 18**.

Fig. 4 is one system configuration in accordance with the present invention. The system is comprised of four control units:

- Access control unit **410** – for realizing the media access control protocol as specified in **Fig. 11**
- Antenna control unit **420** – for coordinating the selection operation among the multiple antenna sectors **450-1** to **450-N** as specified in **Fig. 12**
- Spatial receiving controller **430** – for realizing the receiving operation as specified in **Fig. 13**
- Spatial transmitting controller **440** – for realizing the transmitting operation as specified in **Fig. 14**

The access control unit **410** controls the operation of data packet sending by executing the procedure **1100** in **Fig. 11**, which operates as follows:

- When there is a data packet that needs to be transmitted (or sent) over the wireless channel the access control unit **410**, the access control unit **410** sends a request to send (RTS) signal **1110** (in **Fig. 11**) to the spatial transmitting controller **440**.
- The access control unit **410** then waits until it receives clear to send (RTS) signal **1120** from the spatial receiving controller **430**.
- The access control unit **410** sends Clear to Send (CTS) with the data packet to transmitting controller **440** - **1130**. In which case the message to the transmitting controller **440** may include a transmission schedule at the time the data should be transmitted.

In another embodiment of the current invention, the access control unit **410** controls the operation of data packet sending by following the various IEEE 802.11 standards, e.g., IEEE 802.11a, IEEE 802.11b and IEEE 802.11g.

The antenna control unit **420** has a baseband processor – **422**, controls the operation of Select Antenna Procedure **1200** by executing the procedure specified in **Fig. 12**, which operates as follows:

- The antenna control unit **420** Sends Select Antenna Request to Receiving Controller – **1210** – thenThe antenna control unit **420** Receives Select Antenna Reply From Receiving Controller with Selected Antenna Information – **1220** - then
- The antenna control unit **420** Sends Selected Antenna Information to Transmitting Controller – **1230**.

The antenna control unit **420** also includes a First Buffer **421** for storing selected parameters: electromagnetic signal characteristics for the signal for selected ones of the antenna sectors, selected parts of the digital data received by the spatial receiving controller **430** and by selected ones from the plurality of Receiver/DEMOS (demodulators) **431**. The operation of the plurality of Receiver/DEMOS (demodulators) **431** is controlled by the spatial receiving controller **430**. The plurality of Receiver/DEMOS (demodulators) **431** is coupled to the plurality of RRF/LNAs (Receive RF/Low Noise Amplifiers) **432** for receiving the analog signal through the *N*-to-*R* Switch **433** and the plurality of TRCs (Transmit/Receive (Directional) Couplings) **460** from the plurality of antenna sectors **450**.

The spatial receiving controller **430** operates continuously, as described in **Fig. 13**, performing the Selecting Antenna Algorithm: Continuous Direction-of-Arrival Operation **1300** in five steps:

- Step **1310** – Select Antenna Sector *i* - According to a Predefined Order
- Step **1320** – Measure Predefined Reception Characteristics of Sector *i* – which includes RFDC/RFID (Radio Frequency Data Communications/Radio Frequency Identification), RSSI (Received Signal Strength Indicator) that provides a signal for logic circuit processing that is a function of received RF signal strength. RSSI is used both by the access control unit **410** and the antenna control unit **420**. Step **1330** – Store Reception Characteristics of Sector *i* In Reception Vector
- Step **1340** – Select Antenna Sector From Information Stored in the Reception Vector According to Predefined Signal Characteristics
- Step **1350** – Send Selected Antenna Information To Antenna Control Unit
- Then back to Step **1310**.

The antenna control unit **420** has a baseband processor **422**, and controls the operation of the Spatial Transmitting Controller **440**. The Spatial Transmitting Controller **440** controls the operation of the transmitter modulator **441** and the *T*-to-*N* switch **443** in order to send data packets in the selected direction, by executing the procedure specified in **Fig. 14**. The operation of the Spatial Transmitting Controller **440** has three continuous decision steps:

- Decision Step 1 – **1410**: Received Selected Antenna Information From Antenna Control Unit? If NO THEN GOTO Decision Step 2 – **1430**, ELSE Select Antenna Sector Using Information Received Configure *N*-to-*R* Switch **1420**.
- Decision Step 2 – **1430**: Received Request to Send From Access Control Unit? If NO THEN GOTO Decision Step 3 – **1450**, ELSE Transmit Request to Send Via Selected Antenna Sector Using the Selected Antenna Information Received From Antenna Control Unit **1440**.
- Decision Step 3 – **1450**: Received Clear to Send & Data Packet From Access Control Unit? If NO THEN GOTO Decision Step 1 – **1410**, ELSE Transmit Data Packet through *N*-to-*R* Switch to Selected Antenna Sector Using the Selected Antenna Information Received From Antenna Control Unit **1460**.

Fig. 5 is a functional description of the mobile device (MD) **130** and the antenna system (AS) **150** that is comprised of *N* antenna sectors **450** that are coupled to an antenna control unit by means of switches **433** and **433**, transmit/receive coupling (TRC) **460**, TRF (transmit radio frequency), RRF (receive radio frequency), receivers and transmitters. Specifically, in this functional description, the TRFs are located to couple the *T*-to-*N* switch **443** to the TRCs and the RRFs are located to couple the TRCs to the *N*-to-*R* switch **433**.

The wireless network adapter that is described in **Fig. 5** is similar to the wireless network adapter that is described in **Fig. 4**. However, in **Fig. 5** the plurality of Receiver/DEMOS (demodulators) **431** are coupled to the *N*-to-*R* Switch **433**, which is coupled to the plurality of RRF/LNAs (Receive RF/Low Noise Amplifiers) **432** for receiving the analog signal through and the plurality of TRCs (Transmit/Receive (Directional) Couplings) **460** from the plurality of antenna sectors **450**. While in the wireless network adapter that is described in **Fig. 4**, the plurality of RRF/LNAs (Receive RF/Low Noise Amplifiers) **432** are located between the *N*-to-*R* Switch **433** and the plurality of Receiver/DEMOS (demodulators) **431**. On the transmit side of the wireless network adapter that is described in **Fig. 5**, the TRF/PA (Transmit RF (Radio Frequency) / Power Amplifier) **442** is coupled the *T*-to-*N* switch **443** and to the plurality of antenna sectors **450** through the plurality of TRC (Transmit/Receive (Directional) Coupling) **460**. While in the wireless network adapter that is described in **Fig. 4**, the plurality of the TRF/PAs

(Transmit RF (Radio Frequency) / Power Amplifiers) **442** is coupled the *T-to-N* switch **443** and to the plurality of transmitter/MODs (modulators) **442**.

Fig. 7 is a system configuration of an antenna system, wireless network adapter, comprised of two moveable antenna systems. **Fig. 8** is a diagram of a moveable antenna system that can be directed in 3-D space by means of two motors. **Fig. 15** is a flow chart describing the select direction algorithm: continuous direction-of-arrival operation of the moveable receiving controller. **Fig. 16** is a flow chart describing the operation of the moveable transmitting controller.

The operation of the access control unit **410** in **Fig. 7** is described in the flow chart of **Fig. 11 – Send Data Packet Procedure: 1100**.

- When there is a data packet that needs to be transmitted (or sent) over the wireless channel, the access control unit **410** sends a request to send (RTS) signal **1110** (in **Fig. 11**) to the spatial transmitting controller **440**.
- The access control unit **410** then waits until it receives clear to send (RTS) signal **1120** from the spatial receiving controller **430**.
- The access control unit **410** sends Clear to Send (CTS) with the data packet to transmitting controller **440 - 1130**. The message and to the transmitting controller **440** may include a transmission schedule on the time the data should be transmitted.

The operation of the antenna control unit **420** in **Fig. 7** is described in the flow chart of **Fig. 12 – Select Antenna Procedure: 1200**.

- The antenna control unit **420** sends Select Antenna Request to Receiving Controller – **1210** – then The antenna control unit **420** receives Select Antenna Reply From Receiving Controller with Selected Antenna Information – **1220** – then
- The antenna control unit **420** sends Selected Antenna Information to Transmitting Controller – **1230**.

The moveable operation of the antenna system in **Fig. 7** consists of two controllers:

- Moveable Receiving Controller **730** and is further specified in **Fig. 15**, and
- Moveable Transmitting Controller **740** and is further specified in **Fig. 16**.The

receiving operation of the moveable operation of the antenna system of **Fig. 7** as shown in **Fig.**

15 – Select Direction Algorithm – consists of five computing steps: Continuous Direction-of-Arrival Operation 1500:

- Step **1510** – Select Direction in 3-D Space: Move First Motor to Phi Direction
Move Second Motor to Theta Direction According to a Predefined Order
- Step **1520** – Measure Predefined Reception Characteristics of Direction $v(\text{Phi}, \text{Theta})$
- Step **1530** – Store Reception Characteristics of Direction $v(\text{Phi}, \text{Theta})$ In Reception Vector
- Step **1540** – Select Antenna Direction $v(\text{Phi}, \text{Theta})$ From Information Stored in the Reception Vector According to Predefined Signal Characteristics
- Step **1550** – Send Selected Antenna Information (with Direction $v(\text{Phi}, \text{Theta})$) To Antenna Control Unit
- GOTO Step **1510**.

The operation of the Moveable Transmitting Controller **740** in **Fig. 16** has three continuous decision steps:

- Decision Step 1 – **1610**: Received Selected Antenna Information with Direction $v(\text{Phi}, \text{Theta})$ From Antenna Control Unit? If NO THEN GOTO Decision Step 2 – **1630**, ELSE Direct Second Moveable Antenna in Direction $v(\text{Phi}, \text{Theta})$ **1620**.
- Decision Step 2 – **1630**: Received Request to Send From Access Control Unit? If NO THEN GOTO Decision Step 3 – **1650**, ELSE Transmit Request to Send in Direction $v(\text{Phi}, \text{Theta})$ that was provided by the Antenna Control Unit **1640**.
- Decision Step 3 – **1650**: Received Clear to Send & Data Packet From Access Control Unit? If NO THEN GOTO Decision Step 1 – **1610**, ELSE Transmit Data Packet through Second Moveable Antenna in Direction $v(\text{Phi}, \text{Theta})$ Using the Selected Antenna Information Received From Antenna Control Unit **1660**.

The Access Control Unit **410** in **Fig. 7** operates as described in **Fig. 11**. The Antenna Control Unit **420** in **Fig. 7** operates as described in **Fig. 12**.

The system in **Fig. 7** consists of two RRF/LNA-A/D (Receiver Radio Frequency/Low Noise Amplifier – Analog to Digital Conversion) & Direction of Arrival (DoA) Receiver **731-1** and **731-2**. The first RRF/LNA-A/D **731-1** is connected to the first Moveable Antenna System

(AS) **750-1** and is used to continuously scan a predefined part of the three-dimensional space and record the quality of the analog and digital signals that are received in various directions in said predefined part of the three-dimensional space. The recorded quality of the analog and digital signals is then transferred to the Antenna Control Unit **420**. The operation of the first Moveable Antenna System (AS) **750-1** and the first RRF/LNA-A/D **731-1** is performed by the Moveable Receiving Controller **730**, which performs three basic functions:

- Directs the first Moveable Antenna System (AS) **750-1** in predefined set of direction in the predefined part of the three-dimensional space using the first Motion Control Signal **770-1**,
- Controls the recording quality of the analog and digital signals in the predefined set of direction in the predefined part of the three-dimensional space by the first RRF/LNA-A/D **731-1**, which receives the RF (radio frequency) signal **780-1** from the first Moveable Antenna System (AS) **750-1**, and
- Controls the receiving operations of data packets by the second RRF/LNA-A/D **731-2**, which receives the RF (radio frequency) signal from the second Moveable Antenna System (AS) **750-2** and then transfers the data packet to the Access Control Unit **410**.

The second Moveable Antenna System (AS) **750-2** in **Fig. 7** is connected to both the second RRF/LNA-A/D **731-2** and TRF/PA-D/A (Transmit RF/Power amplifier – digital-to-analog conversion) Transmitter **740** by means of the TRC (Transmit/Receive (Directional) Coupling) **760**. The second Moveable Antenna System (AS) **750-2** is controlled by the second Motion Control Signal **770-1** received from the Antenna Control Unit **420**. The operation of the TRF/PA-D/A (Transmit RF/Power amplifier – digital-to-analog conversion) Transmitter **740** is controlled by the Moveable Transmitting Controller, which receives data packets for transmission the selected direction $v(\text{Phi}, \text{Theta})$ from the Access Control Unit **410** – as described in **1660** in **Fig. 16**. The operation of Antenna Systems (ASs) **750-1** and **750-2** are described in more detail in **Fig. 8**. Each of the two Antenna Systems (ASs) **750-1** and **750-2** is a 3-D Moveable Antenna System that is controlled by two Moveable Directions: Motion Control Signal in Two Circular Coordinates: $v(\text{Phi}, \text{Theta})$, which are controlled by two signals:

- Move to Theta Direction Signal **820-H** – horizontal motion, and

- Move to Phi Direction Signal **820-V** – vertical motion.

The Antenna Systems (ASs) **750-1** and **750-2** motion can be realized by various means such as electric step-motor. As shown in **Fig. 8.**, there are two step motors: step-motor 1 **810-H** is controlled by Direction Signal **820-H**, and step-motor 2 **810-V** is controlled by Direction
5 Signal **820-V**.

As shown in **Fig. 7** and **Fig. 8**, selected ones of the antenna sectors are electro-mechanically steered antennas. The electro-mechanically steered antennas cover a predefined range in at least one of: two dimensional space and three-dimensional space, as defined in **Fig. 3**. The electro-mechanically steered antennas are moveable by at least one of: a step-motor, an
10 electric motor, an electric field, and a magnetic field.

Fig. 9 is a wireless network adapter configuration of an antenna system that is comprised of a plurality of antenna sectors—each comprising a plurality of antenna elements. **Fig. 17** is a flow chart describing the select direction algorithm: continuous direction-of-arrival operation of the array-receiving controller. **Fig. 18** is a flow chart describing the operation of the array-
15 transmitting controller. The general operation principles of the adapter in **Fig. 9** are similar to the wireless network adapter in **Fig. 4** **Fig. 5**. The wireless network adapter in **Fig. 9** consists of N Antenna Sectors, **950-1** to **950-N**, with k Antenna Elements each. The k Antenna Elements are used to form a beam in specific direction in the 3-D space. The beam forming of each antenna sector is done responsive to plurality of circuits for synthesizing the pattern of k antenna
20 elements' digital beam forming (DBF) that is part of:

- Array & RRF/LNA (Receive RF/Low Noise Amplifier) & Receiver **931-1** to **931-R**
- Array & TRF/PA (Transmit RF/Power amplifier) & Transmitter **941-1** to **941-T**
- Array & RRF/LNA are coupled to: (1) the N Antenna Sectors, **950-1** to **950-N**, through an N -to- R Switch **933**, (2) the Array Receiving Controller **930**, (3) the
25 Antenna Control Unit **420** (see **Fig. 12**) for receiving direction information, and (4) the Access Control Unit **410** (see **Fig. 11**) for transferring data packets received from the wireless channel.
- Array & TRF/PA are coupled to: (1) the N Antenna Sectors, **950-1** to **950-N**, through an N -to- T Switch **943**, (2) the Array Transmitting Controller **940**, (3) the
30 Antenna Control Unit **420** (see **Fig. 12**) for receiving direction information, and (4)

the Access Control Unit **410** (see **Fig. 11**) for receiving data packets to be transmitted over the wireless channel.

The wireless network adapter in **Fig. 9** further consists of two controllers: (1) Array Receiving Controller **930** – see **Fig. 17** and (2) Array Transmitting Controller **940** – see **Fig. 18**.
The two controllers are responsible for the actual operations required for receiving and transmitting data packets. The two controllers are described next.

The Array Receiving Controller in **Fig. 9** as shown in **Fig. 17** – Select Direction Algorithm consists of five computing steps: Continuous Direction-of-Arrival Operation 1700:

- Step **1710** – Select Direction in 3-D Space: Move Array Antenna in Direction $v(\text{Phi}, \text{Theta})$ According to a Predefined Order
- Step **1720** – Measure Predefined Reception Characteristics of Direction $v(\text{Phi}, \text{Theta})$
- Step **1730** – Store Reception Characteristics of Direction $v(\text{Phi}, \text{Theta})$ In Reception Vector
- Step **1740** – Select Antenna Direction $v(\text{Phi}, \text{Theta})$ From Information Stored in the Reception Vector According to Predefined Signal Criteria
- Step **1750** – Send Selected Antenna Information (with Direction $v(\text{Phi}, \text{Theta})$) To Antenna Control Unit
- GOTO Step **1710**.

The operation of the Array Transmitting Controller **940** in **Fig. 18** has three continuous decision steps:

- Decision Step 1 – **1810**: Received Selected Antenna Information with Direction $v(\text{Phi}, \text{Theta})$ From Antenna Control Unit? If NO THEN GOTO Decision Step 2 – **1830**, ELSE Direct Second Array Antenna in Direction $v(\text{Phi}, \text{Theta})$ **1820**.
- Decision Step 2 – **1830**: Received Request to Send From Access Control Unit? If NO THEN GOTO Decision Step 3 – **1850**, ELSE Transmit Request to Send in Direction $v(\text{Phi}, \text{Theta})$ that was provided by the Antenna Control Unit **1640**.
- Decision Step 3 – **1850**: Received Clear to Send & Data Packet From Access Control Unit? If NO THEN GOTO Decision Step 1 – **1810**, ELSE Transmit Data

Packet through Second Array Antenna in Direction $\nu(\text{Phi}, \text{Theta})$ Using the
Selected Antenna Information Received From Antenna Control Unit **1860**.

Fig. 10 is a wireless network adapter configuration of an antenna system that is a variation of the wireless network adapter configuration of an antenna system in **Fig. 9**. The system in **Fig. 10** comprises three antenna segments in the x , y and z directions—each is comprised of k antenna elements.

The system in **Fig. 10** includes an Array Receiving Controller that operates according to **Fig. 17** which is a flow chart describing the select direction algorithm: continuous direction-of-arrival operation of the array receiving controller. The system in **Fig. 10** includes an Array Transmitting Controller that operates according to **Fig. 18** which is a flow chart describing the operation of the array transmitting controller.

As shown in **Fig. 10**, this configuration of wireless network adapter consists of three Antenna Sectors—each with k Antenna Elements. Each sector is has a direction in 3-D space: (1) X direction – 1010- x , (1) Y direction – 1010- y , and (1) Z direction – 1010- x . Each of the three sectors is coupled to a corresponding module that consists of: RF (radio frequency) with D/A (digital-to-analog conversion) – A/D (analog-to-digital conversion) – 1020- x , 1020- y and 1020- z . The three RF with D/A-A/D modules are coupled to and controlled by both the Array Transmitting Controller **940** and the Array Receiving Controller **930**. The Array Transmitting Controller **940** and the Array Receiving Controller **930** are coupled to and control the operation of both Array Transmitter **941** and Array Receiver **931**. Both Array Transmitter **941** and Array Receiver **931** are coupled to the three antenna sectors: **1020- x** , **1020- y** and **1020- z** , for transmitting and receiving digital data units.

As shown in **Fig. 9** and **Fig. 10**, selected ones of the antenna sectors are array antennas. Each selected one of the array antennas direct its electromagnetic signal in a direction defined using circular three-dimensional coordinates Phi and Theta (as shown in **Fig. 3**). The respective defined region of the transmissions emitted by the array antennas overlaps a defined part of the three-dimensional space.

Special Operation Modes:

Two special operation modes are described herein:

1. In **Fig. 19**, for end (mobile) device transmitting and receiving on different radio frequencies, **Fig. 19** is a flow chart describing the operation of an end (mobile) device that is capable of transmitting and receiving on different wavelengths, and
2. In **Fig. 20**, for end (mobile) device locking on a specific access point, **Fig. 20** is a flow chart describing the operation of an end (mobile) device that is capable of selecting and locking its operation to a specific selected access point, while continuously selecting an antenna sector in which the received signal has the most desired properties.

In some cases, it is necessary to transmit and receive using two different radio frequencies; consequently, the transmit and receive operations are not symmetric. Specifically, the transmit and receive operations may have to use different antenna sectors – e.g., see the wireless network adapters in **Fig. 4** and **Fig. 5**. With different transmit and receive frequencies the following observations can be made regarding the two operations:

1. Receive operation – determining the best receiving antenna sector can be done as described in **Fig. 4**, **Fig. 5**, **Fig. 11**, **Fig. 12**, **Fig. 13**, and **Fig. 14**.
2. Transmit operation – determining the best transmitting antenna sector can be done by getting feedback from the receiver on the other side, which is usually the access point (AP).

The transmit operation in the case of different transmit and receive frequencies is described in **Fig. 19** and has the following six steps:

- Step 1: **1910** – Select Antenna Sector i According to a Predefined Order
- Step 2: **1920** – Through Sector i Send RTS (request to send) message with Request to Receive Reception Characteristics to the receiving side,—typically the access point.
- Step 3: **1930** – Wait until Receive CTS (clear to send) message with Reception Characteristics for Sector i from the receiving side—typically the access point.
- Step 4: **1940** – Store Reception Characteristics of Sector i In Transmit Reception Vector
- Step 5: **1950** – Select Transmit Antenna Sector From Information Stored in the Transmit Reception Vector According to Predefined Signal Characteristics;

consequently, the transmit antenna sector (as described in **Fig. 4** and **Fig. 5**) is continuously updated

- Step 6: **1960** – Send Selected Transmit Antenna Information To Antenna Control Unit 420
- GOTO Step 1.

Fig. 20 describes the procedure by which the end (mobile) device locks on a specific access point. This configuration may be needed for traffic engineering when there is a plurality of access points and a large number of mobile devices, in an attempt to balance the load on the plurality of access points. The operation in this case is similar to the operation of the wireless network adapters described in **Fig. 4**, **Fig. 5** and **Fig. 13** (Select Antenna Algorithm: Continuous Direction-of-Arrival Operation **1300**). Selecting the antenna sector that performs best with respect to a specific access point is performed in the following five iterative steps:

- Step 1: **2010** – Select Antenna Sector i According to a Predefined Order.
- Step 2: **2020** – Measure Predefined Reception Characteristics of Sector i For Specific Access Point Identification.
- Step 3: **2030** – Store Reception Characteristics of Sector i with Access Point Identification In Reception Vector.
- Step 4: **2040** – Select Antenna Sector from Information Stored in the Reception Vector According to Predefined Signal Characteristics for a Specific Access Point Identification.
- Step 5: **2050** – Send Selected Antenna Information to Antenna Control Unit **420**.
- GOTO Step 1.

As shown in **Fig. 4**, **Fig. 5**, **Fig. 7** and **Fig. 9**, the system is also comprised of a receiving switch. The receiving controller is selectively coupled to at least one of the antenna sectors by means of the receiving switch. The system is also comprised of a plurality of receiver radio frequencies (RRF). The receiving switch has N inputs and R outputs. The N inputs are selectively connected to the antenna sectors, and R outputs are connected to selected ones of the plurality of the RRF.

As shown in **Fig. 4**, **Fig. 5**, **Fig. 7** and **Fig. 9**, the system is also comprised of a transmitting switch. The transmitting controller is selectively coupled to at least one of the antenna sectors by

means of the transmitting switch. The system also comprised a plurality of receiver radio frequencies (RRF). The receiving switch has T inputs and N outputs. The N outputs are selectively connected to the antenna sectors, and T inputs are connected to selected ones of the plurality of the RRF.

5 As shown in **Fig. 4, Fig. 5, Fig. 7 and Fig. 9**, the receiving controller is selectively coupled to the antenna sectors in a predefined order. The receiving controller is also shown selectively coupled to the antenna sectors in a random order.

10 As shown in **Fig. 4, Fig. 5, Fig. 7 and Fig. 9**, the receiving controller is selectively coupled to the antenna sectors in at least one of the following patterns: reoccurring, one at a time, two at a time, three at a time, bisection, opposite directions, intersecting sets.

 As shown in **Fig. 4, Fig. 5, Fig. 7 and Fig. 9**, the received electromagnetic signal characteristics are converted to digital signals with control information and data information used by the receiving controller to select at least one of the antenna sectors.

15 As shown in **Fig. 1, Fig. 4, Fig. 5, Fig. 7, and Fig. 9**, the preferred embodiment is a system for transmitting a plurality of data packets comprising: a first buffer; a plurality of antenna sectors; a receiving controller; a transmitting controller. The receiving controller is selectively coupled to at least one of the antenna sectors in order to measure their received electromagnetic signal characteristics and then stores them in the first buffer. The transmitting controller is coupled, based upon the received electromagnetic signal characteristics stored in the first buffer, 20 to at least one of the antenna sectors within a first predefined time interval prior to the transmission of at least one data packet. At least one of the receiving controller and the transmitting controller selects at least one of the antenna sectors based on the received electromagnetic signal characteristics stored in the first buffer.

25 As shown in **Fig. 1, Fig. 4, Fig. 5, Fig. 7, and Fig. 9**, the receiving controller is selectively coupled to the antenna sectors in a defined order responsive to the electromagnetic signal characteristics stored in the first buffer, and is selectively coupled to the antenna sectors in at least one of the following patterns responsive to the electromagnetic signal characteristics stored in the first buffer: one at a time, two at a time, three at a time, bisection, opposite directions, intersecting sets.

Fig. 1, Fig. 4, Fig. 5, Fig. 7, and Fig. 9, show a wireless device and an antenna system coupled to one another by means of at least one of the following: plurality of coax cables, multi-lead coax cable, parallel data connection, serial data connection, parallel data and control connection, parallel data, timing and control connection, PCMCIA interface, USB, IEEE 1394 (Fire-Wire).

Fig. 1, Fig. 4, Fig. 5, Fig. 7, and Fig. 9 show that the wireless device contains at least one of: the plurality of antenna sectors, the receiving controller; the transmitting controller and the first buffer.

Fig. 1, Fig. 4, Fig. 5, Fig. 7, and Fig. 9, show that the antenna system contains at least one of: the plurality of antenna sectors, the receiving controller; the transmitting controller and the first buffer.

Fig. 1, Fig. 4, Fig. 5, Fig. 7, and Fig. 9, show an access control unit that is part of at least one of: the wireless device and the antenna system.

Fig. 1, Fig. 4, Fig. 5, Fig. 7, and Fig. 9, show an antenna control unit that is part of at least one of: the wireless device and the antenna system.

Fig. 1, Fig. 4, Fig. 5, Fig. 7, and Fig. 9, show an antenna selector processor that processes the received electromagnetic signal characteristics stored in the first buffer to select at least one of the antenna sectors for transmission of data packets. The antenna selector processor also performs parts of at least one of the following protocols: IEEE 802.11, IEEE 802.15, IEEE 802.16, CDMA 2000, WCDMA, UMTS, GPRS, 2.5G, 3G, 4G, 5G, GSM.

Fig. 1, Fig. 4, Fig. 5, Fig. 7, and Fig. 9, show the system further comprised of an antenna control unit which sends a request to send (RTS) signal to the transmitting controller and receives a clear to send (CTS) from the receiving controller. The RTS signal is generated responsive to the arrival of at least one data packets.

Fig. 1, Fig. 4, Fig. 5, Fig. 7, and Fig. 9, show the system further comprised of an access control unit, which sends a request to send (RTS) signal to the transmitting controller and wherein the access control unit which receives a clear to send (CTS) from the receiving controller. The RTS signal is generated responsive to the arrival of at least one data packets.

Description of Antenna System 150 Structures with Plurality of Antenna Sectors 160:

The antenna system 150 structures are described in: **Fig. 6, Fig. 21, Fig. 22, Fig. 23, Fig. 26, Fig. 27, Fig. 29 and Fig. 30.**

Fig. 6 is a three-dimensional diagram of an antenna system with a plurality of antenna sectors. A cylindrical configuration **610** is illustrated with six antenna sectors forming a hexagonal structure. The **620** structure is a configuration with six antenna sectors. The **630** structure is a configuration with eight-antenna sectors. The **640** structure is a polyhedron configuration with twelve antenna sectors.

As shown in **Fig. 6**, the directional antennas are arranged in a predefined pattern in at least one of: octahedron, pentagon, cube, pyramid, sectorized cylinder, polyhedron, Pentagondodecahedron. The predefined pattern orients the directional antennas on selected sides of at least one of: mobile device, communicating device, base station, access point, pole, cellular phones, laptop computer, PDA, WLL system.

The Antenna System (AS) – **150** in **Fig. 6** consists of a Spatial Receiving Controller; Spatial Transmitting Controller; a Receiver Radio Frequency – RRF; a Transmitter Radio Frequency – TRF; a *N*-to-*R* Switch and a *T*-to-*N* Switch (see also **Fig. 4** and **Fig. 5**).

Each side of face of the four polygons in **Fig. 6** represent a possible antenna sector **620** has six faces on a cylinder forming hexagonal structure, and thus, it can accommodate six possible antenna sectors. **620** has six faces on a cube, and thus, it can accommodate six possible antenna sectors. **630** has eight faces on an octahedron, and thus, it can accommodate eight possible antenna sectors. **640** has twelve faces on a sphere, and thus, it can accommodate twelve possible antenna sectors.

Fig. 21 is a schematic description of a planar array in which all of the elements, both active and parasitic, are in one plane. A Planar antenna can be implemented using printed circuit process, and thus, is often called a printed antenna or antenna's "patches."

Printed circuit antennas are important to telecommunications because of advantages such as low cost, light weight, low profile and the potential for integration with active solid-state devices. For the past decade, there have been significant contributions to printed circuit antenna technology, and specific progress has been made in printed circuit antenna technology; particularly, in the areas of bandwidth enhancement and MMIC phased-array antenna

development. The objective has been to develop low-cost, high-efficiency printed circuit antennas through experimentation and analysis. Micro-strip antennas are typically constructed on a printed circuit board (PCB).

An antenna is a device that is made to efficiently radiate and receive radiated electromagnetic waves. There are several important antenna characteristics that should be considered when choosing an antenna for application: Antenna radiation patterns, Power Gain, Directivity, and Polarization.

Power Gain: The power gain of an antenna is a ratio of the power input to the antenna to the power output from the antenna. This gain is most often referred to with the units of dBi, which is logarithmic gain relative to an isotropic antenna. An isotropic antenna has a perfect spherical radiation pattern and a linear gain of one.

Directivity: The directive gain of an antenna is a measure of the concentration of the radiated power in a particular direction. It may be regarded as the ability of the antenna to direct radiated power in a given direction. It is usually a ratio of radiation intensity in a given direction to the average radiation intensity.

Polarization: Polarization is the orientation of electromagnetic waves far from the source. There are several types of polarization that apply to antennas. They are Linear--Vertical, Horizontal and Oblique; and circular--Circular Right Hand (RHCP); Circular Left Hand (LHCP), Elliptical Right Hand and Elliptical Left Hand. Polarization is most important for maximizing performance from the antennas. Optimal performance requires proper polarization matching of the transmitting antenna and the receiving antenna.

Selected directional antennas that are relevant include the following:

- **Yagi Antennas:** Yagi antennas consist of an array of independent antenna elements, with only one of the elements driven to transmit electromagnetic waves. The number of elements (specifically, the number of director elements) determines the gain and directivity. Yagi antennas are not as directional as parabolic dish antennas, but more directional than flat panel antennas.
- **Flat Panel antennas:** Flat panel antennas are just that, configured in a patch type format and physically in the shape of a square or rectangle. Flat panel antennas are quite directional as they have most of their power radiated in one direction in both

the vertical and horizontal planes. Flat panel antennas can be made to have varying amounts of gain based on the construction. This can provide excellent directivity and considerable gain.

- 5 • **Parabolic Dish antennas:** Parabolic dish antennas use physical features as well as multiple element antennas to achieve extremely high gain and sharp directivity. These antennas use a reflective dish in the shape of a parabola to focus all received electromagnetic waves on the antenna to a single point. The parabolic dish also works to catch all the radiated energy from the antenna and focus it in a narrow beam when transmitting. As shown in **Figure 5**, the parabolic dish antenna is very
10 directional. By harnessing all of the antenna's power and sending it in the same direction, this type of antenna is capable of providing high gain.
- 15 • **Slotted Antennas:** The slotted antenna exhibits radiation characteristics that are very similar to those of the dipole. The elevation and azimuth patterns are similar to those of the dipole, but its physical construction consists only of a narrow slot cut
20 into ground plane. As with microstrip antennas mentioned below, slotted antennas provide little antenna gain, and do not exhibit high directionality, as evidenced by their radiation plots and their similarity to the dipoles. Their most attractive feature is the ease with which they can be constructed and integrated into an existing design, and their low cost. These factors most often offset their mediocre
25 performance characteristics.
- **Microstrip Antennas:** Microstrip antennas can be made to emulate many of the different styles of antennas explained above. Microstrip antennas offer several tradeoffs that need to be considered. Because they are manufactured with PCB traces on actual PCB boards, they can be very small and lightweight. This comes at
the cost of not being able to handle as much output power as other antennas, and they are made for very specific frequency ranges. In many cases, limiting the frequencies that can be received is actually beneficial to the performance of a radio. Due to this characteristic, micro strip antennas are not well suited for wideband communications systems.

The antenna system **150** in **Fig. 21** consists of four Directional / Polarized Planar Array Antenna Sectors, wherein each antenna sector can be a micro-strip phased/patch array/flat panel:

- **2121** – Antenna Sector 1 receives the RF signal **2111** from the Antenna Switch Structure **2110**,
- **2122** – Antenna Sector 1 receives the RF signal **2112** from the Antenna Switch Structure **2110**,
- **2123** – Antenna Sector 1 receives the RF signal **2113** from the Antenna Switch Structure **2110**, and
- **2124** – Antenna Sector 1 receives the RF signal **2114** from the Antenna Switch Structure **2110**.

The unused antenna sectors can be connected to electric ground potential **2100G**. The electric ground potential **2100G** may also be also part of the design and implementation of the directional antenna sectors; however, the ground design and implementation are only selectively shown.

Fig. 22 is a is a schematic description of an Antenna System **150**, consisting of six directional and/or polarized planar array antenna sectors which are arranged on a cylinder, so that each antenna sector can be a micro-strip phased/patch array/flat panel. The six antenna sectors are selected and controlled via antenna switch structure **2210**, in the following way:

- **2221** – Antenna Sector 1 receives the RF signal **2211** from the Antenna Switch Structure **2210**,
- **2222** – Antenna Sector 1 receives the RF signal **2212** from the Antenna Switch Structure **2210**,
- **2223** – Antenna Sector 1 receives the RF signal **2213** from the Antenna Switch Structure **2210**,
- **2224** – Antenna Sector 1 receives the RF signal **2214** from the Antenna Switch Structure **2210**,
- **2225** – Antenna Sector 1 receives the RF signal **2215** from the Antenna Switch Structure **2210**, and
- **2226** – Antenna Sector 1 receives the RF signal **2216** from the Antenna Switch Structure **2210**.

The antenna system in **Fig. 22** may further consist of top and bottom antenna sectors at the top and the bottom of the cylinder. The unused antenna sectors can be connected to electric ground potential **2200G**. The electric ground potential **2200G** may also be also part of the design and implementation of the directional antenna sectors; however, the ground design and implementation are only selectively shown.

Fig. 23 is a schematic description of an Antenna System **150**, consisting of four directional parabolic-dish-reflector or Yagi/Tube-like antenna sectors that can be used in the current invention. The four antenna sectors are selected and controlled via antenna switch structure **2310**. A parabolic antenna consists of a parabolic reflector and a radiating or receiving element at or near its focus. Parabolic antennas are directive and include a preliminary source and a parabolic reflector to focus the energy.

The four Directional Parabolic-dish-reflector Yagi/Tube-like antenna sectors are selected and controlled via antenna switch structure **2310** in the following way:

- **2321** – Antenna Sector 1 receives the RF signal **2311** from the Antenna Switch Structure **2310**,
- **2322** – Antenna Sector 1 receives the RF signal **2312** from the Antenna Switch Structure **2310**,
- **2323** – Antenna Sector 1 receives the RF signal **2313** from the Antenna Switch Structure **2310**, and
- **2324** – Antenna Sector 1 receives the RF signal **2314** from the Antenna Switch Structure **2310**.

The unused antenna sectors can be connected to electric ground potential **2300G**. The electric ground potential **2300G** may also be also part of the design and implementation of the directional antenna sectors; however, the ground design and implementation are only selectively shown.

Fig. 24 is a functional description of the mobile device (MD) and the antenna system (AS) comprised of N antenna sectors coupled to a separate access control unit with a baseband processor by means of transmit/receive coupling (TRC), TRF – transmit RF (radio frequency) and RRF – receive RF. The plurality of separate access control units with baseband processors are coupled to an antenna control unit. This mobile device configuration does not require a

switch for switching among the plurality of antenna sectors. In the configuration shown in **Fig.**

24 the Access Control Unit and Baseband Processor are replicated **2410-1** to **2410-N** for controlling the operation of each one of the N directional antenna sectors, which facilitate the soft switch operation in accordance with this invention. The antenna control unit **2420**

determines which one of the N Access Control Unit and Baseband Processor should be used – at least one should be selected prior to the transmission of data packets.

Fig. 24 is a wireless system for transmitting and receiving a plurality of data packets. The system consists of a plurality of directional antenna sectors **2450-1** to **2450-N**—each having a respective three-dimensional region for transmitting and receiving electromagnetic signals. The system in **Fig. 24** has a plurality of access control units—each having a baseband processor **2410-1** to **2410-N** and an antenna control unit **2420**. Each directional antenna sector transmits an electromagnetic signal in a predefined region in three-dimensional space when coupled to a selected one of the access control with baseband processors **2410-1** to **2410-N**.

The directional antenna sectors are coupled to at least one selected one of the access control units **2410-1** to **2410-N** for receiving data packets and for measuring at least one received electromagnetic signal analog and digital characteristics. Selected received electromagnetic signal characteristics are transferred to the antenna control unit **2420**. The antenna control unit selects at least one of the access control units processor **2410-1** to **2410-N** within a first predefined time interval prior to the transmission of at least one data packet responsive to the received electromagnetic analog and digital signal characteristics.

The access control units **2410-1** to **2410-N** are comprised of at least one of: 802.11 wireless network adapter, 802.15 wireless network adapter, 802.16 wireless network adapter, 3G cellular phone, 4G cellular phone, mobile device, laptop computer, personal computer, personal digital assistant, cellular phone, 2.5G cellular phone, 3G device, 4G device, 5G device, multimedia devices, GPS (global positioning system) receiver, base stations, wireless access points, access routers, and packet switch line card.

The access control units **2410-1** to **2410-N** are coupled to a USB hub coupled to the antenna control unit **2420**. The antenna system **150** in **Fig. 24** shows each of the plurality of access control units utilizing an 802.11-based device coupled to a USB hub and each coupled to a respective plurality of directional antenna sectors.

Fig. 25 is a description of directional flat panel antenna sector **2500** design principles as a function of: (1) the flat panel rectangle dimensions L1-length and L2-width, and (2) the wavelength lambda. The L1-by-L2 flat panel antenna sector is constructed so that L1 is in the x-y plane and L2 is in the z direction (90 degree or perpendicular to the x-y plane). As shown in **Fig. 26**, the vertically stackable directional flat panel antenna sectors are put one on top of the other in the z direction. For example, the height of ten vertically stackable directional flat panel antenna sectors is ten times L2 (since L2 is in the z direction). However, in some cases, in order to better cover the three-dimensional space with the directional antenna sectors, each flat panel:

- L1 may be tilted in the z direction, and
- L2 may be tilted in a defined angle with respect to the x-y plane.

As shown in **Fig. 25**, the design of the flat panel antenna has the following approximated properties:

2511. $g\text{-max} \approx 4 \cdot (3.14) \cdot \{(L1 \cdot L2) / (\text{Lambda}^2)\}$ [Lambda = speed-of-light/Frequency]
[L1*L2 is the rectangular area of antenna aperture in cm²]

2512. Lambda/L1 and Lambda/L2 are the beam widths – in radians (each radian is 57.3 degrees), which implies that for Lambda=2 cm (15 GHz), L1=4 cm and L2=1 cm, the electromagnetic beam will have the following shape: (2/4)*57.3=28.65 degrees by (2/1)*57.3=114.6 degrees. This formulation implies that the electromagnetic beam opening is inversely proportional to the length and width of the flat panel antenna.

2513. Antenna Gain: $G(\text{db}) = 10 \log_{10}(g\text{-max})$ and for the above example:

$$G(\text{db}) \approx 10 \log_{10} 4 \cdot (3.14) \cdot \{(4 \cdot 2) / (2^2)\} = 10 \log_{10} 8 \cdot (3.14) = 14 \text{ db}$$

Generally, flat panel antennas **2500** are just that, configured in a patch type format and physically in the shape of a square or rectangle. Flat panel antennas **2500** are directional as they have most of their power radiated in one direction in both the vertical and horizontal planes. Flat panel antennas can be made to have varying amounts of gain based upon construction. This can provide excellent directivity and considerable gain. A flat panel antenna is constructed in a panel and is usually a phased array antenna. A phased array antenna is an array antenna in which phases shifts can be applied to the signals received or transmitted from individual elements in such a way that the antenna can be electrically steered. An important advantage of a phased array

antenna over a mechanically rotated antenna is the lack of moving parts. One common application of a phased array antenna is as a radar antenna.

Fig. 26 is a functional description of a plurality of vertically stackable flat panel antenna sectors (each antenna sector may be tilted along L1 and/or L2) **2122**. Each antenna sector directs the transmission of its electromagnetic energy to a defined different region in three-dimensional space. The vertically stackable flat panel antennas are placed one on top of the width-side L2 of the other. Consequently, the combined electromagnetic signals of the flat panel antennas may overlap to cover the large part of the three-dimensional space. In the above example: $\Lambda=2$ cm (15 GHz), $L1=4$ cm and $L2=1$ cm – it is possible to cover 180 degrees of the x - y plane with seven flat panel antennas (each antenna covers 28.65 degrees) with 2-3 degrees of overlapping regions between adjacent segments.

The vertically stackable flat panel antennas that are placed in the x - y plane can be rotated and tilted using electric motor as described in **Fig. 8**, and as shown in the Side View **2600** of **Fig. 26**. The moveable directions can be directed with motion control signals in two circular coordinates: $v(\text{Phi}, \text{Theta})$ – **2620-H**: Phi direction signal and **2620-V**: Theta direction signal.

Fig. 27 is a functional description of plurality of vertically stackable Yagi, which is tube-like, directional antenna sectors. Each Yagi/Tube-like antenna sector directs the transmission of its electromagnetic radiation to a defined cone-like region **2354** in three-dimensional space. The vertically stackable Yagi antennas are placed one on top of the other. The radiating element **2343** is placed inside a tube-like reflector **2323**, wherein one side of the tube-like directional Yagi antenna is closed and is part of the reflector **2323**. The vertically stackable tube-like directional Yagi antennas that are placed in the x - y plane can be rotated and tilted using electric motor as described in **Fig. 8**. The moveable directions can be directed with motion control signals in two circular coordinates: $v(\text{Phi}, \text{Theta})$ – **820-H**: Phi direction signal and **820-V**: Theta direction signal.

The antenna system **150** in **Fig. 26** is designed for transmitting and receiving a plurality of data packets. The antenna system **150** consists of a plurality of directional antenna sectors **2122** or **2500** each associated with a respective region of space for transmitting and receiving electromagnetic signals. Each said directional antenna sector **2122** or **2500** is at least one of the following: a flat panel, a planar, a parabolic dish, a slotted, a micro-strip, omni and a Yagi. The

antenna control unit **420** selects the manner in which selected ones of said directional antenna sectors are coupled to the transmitted signal prior to the transmitting of at least one data packet. The antenna control unit **420** selects the manner in which selected ones of said directional antenna sectors are coupled to the received signal prior to receiving of at least one data packet. At least one of selected the receivers **430** is selected by the receiving controller **431** to measure the electromagnetic characteristics of the received signal from selected ones of the plurality of directional antenna sectors **2122** or **2500**.

The receiving controller **431** selects the directional antenna sectors **2122** or **2500** for measuring the analog and digital characteristics of the incoming electromagnetic signal in at least one of: a predefined manner, an arbitrary manner, a random manner, a predefined manner.

As shown in **Figs. 21, 22, 23** and **27**, the directional antenna sector **2122** or **2500** is coupled, at most, in one of the following manners: to transmit a transmitted signal, to receive a received signal, to an electric ground potential; to a predefined electric potential.

As shown in **Figs. 26** and **27**, at least two of the plurality of directional antenna sectors are stackable. The antenna system **150** in **Figs. 26** and **27** is constructed of plurality of flat panel antenna sectors **2500** having a width and a length and are aligned according to orientation of the length. The antenna system **150** in **Figs. 26** and **27** is constructed of plurality of flat panel antenna sectors **2500** having a rectangular shape, a width and a length, and are aligned according to orientation of the width. Each of said rectangle antenna sectors **2500** are vertically stackable flat panel antennas **2500** and are oriented to face a selected predefined direction in space.

Fig. 28 is a functional description of a flat panel antenna sector with multiple “patches” **2810** made of a conducting material, with front view **2810** and side view **2820**. The “patches” **2810** shape, size and how they are placed on the plane are part of the directional design of the flat panel antenna. The “patches” are placed on dielectric material on top of a ground plan **2840** and are fed by an electric signal **2850**. The “patches” **2810** have the electric signal **2850** with different predefined delays, which result in predefined phase shifts of the electromagnetic signal radiated from the “patches” and are part of the directional design of the flat panel antenna. The dielectric material and ground plan **2840** surround the “patches” **2810** with small margins of a small fraction of a wavelength. The typical thickness of the dielectric material and ground plan **2840** is a small fraction of a wavelength. In **Fig. 28**, the L1 and L2 dimensions of the flat panel antenna

determine (approximately) its aperture (as discussed in **Fig. 25**) when the main radiation lobe is perpendicular to the flat panel. However, when the main radiation lobe is not perpendicular but in angle x from perpendicular, the aperture is approximately $L1 * L2 * \cos(x)$. This implies that when the transmission is not perpendicular the antenna gain is smaller – see **Fig. 25**.

5 The flat panel antenna sector **2500** in **Fig. 28** has multiple “patches” **2810** that realize a static-direction phase array structure - “fed” with electric signal that is phase shift via wires of predefined lengths **2850**. **Figs. 7, 8, 17** and **18**, further describe the dynamic-direction and static-direction operations of phase array antenna in the present invention.

10 **Fig. 29** is a functional description of an antenna system utilizing six flat panel directional antenna sectors that are attached on a cylinder **2900** forming hexagonal structure. The antenna system contains an antenna control system **2930** that is connected to a computing device **2940** via a communications channel **2950**. The antenna apparatus in **Fig. 29** is a self-contained antenna structure **2900** (as was also shown in **150/160** in **Figs. 1-2**), comprising a plurality of six flat panel directional antennas: **2921, 2922, 2923, 2924, 2925** and **2925**, arranged on a cylindrical surface forming an hexagonal structure. Each of the plurality of flat panel directional antennas is
15 comprised of a plurality of “patches” **2810** arranged in a pattern as discussed in **Fig. 28**.

20 Alternatively, **Fig. 30** is a functional description of an antenna system utilizing four flat panel directional antenna sectors that are attached to an antenna structure **3000** with arms. The plurality of flat panel directional antennas **3021, 3022, 3023** and **3024** can be supported by a structure **3000** that attaches the plurality of said flat panel directional antennas with arms **3030**. The antenna system contains an antenna control system **2930** connected to a computing device **2940** via a communications channel **2950**.

25 The antenna system in **Figs. 29-30** includes an antenna control system **2930** that executes various wireless media access control protocols such as IEEE 802.11, IEEE 802.15, and IEEE 802.16. It also includes functionality to select at least one of the flat panel antenna sector for transmitting and receiving data packets as described in detail in **Figs. 4-5, 11-14**. The antenna control system **2930** is selectively coupled to the plurality of flat panel directional antennas for selectively communicating data packets to at least one selected one of said plurality of flat panel directional antennas in accordance with predefined criteria determined on a packet-by-packet

basis. The coupling of the antenna control system **2930** to the flat panel antennas is done via a switch as discussed, e.g, in **Figs. 4-5**, or by using high impedance amplifiers.

The flat panel directional antennas provide receiving electromagnetic signals to the antenna control system **2930** for analog and digital analysis in order to select at least one flat panel directional antenna according to predefined criteria. At least one flat panel directional antenna selected for transmitting and receiving data packets is used for transmitting and receiving group of data packets according to predefined criteria. Specifically, the predefined criteria of the received electromagnetic signal characteristics are determined by at least one of the following: analog processing, digital processing, analog filtering, digital filtering, FEC (forward error correction), bit error-rate analysis, time-of-day analysis, propagation delay analysis, transmitter address analysis, and transmitter identification analysis.

The antenna system in **Figs. 29-30** includes an external computing system **2940**, e.g.: a laptop computer, a desktop computer, a personal device, a cell phone. The computing system **2940** is coupled to the antenna control system **2930** via a communications channel **2950** of various predefined types. The computing system **2940** provides is the source and destination of the data packets. The communications channel **2950** utilizes at least one of: a plurality of coax cables, a multi-lead coax cable, a parallel data connection, a serial data connection, a parallel data and control connection, parallel data, a timing and control connection, a PCMCIA (personal computer memory card international association) interface, a USB (universal serial bus), IEEE 1394 (Fire-Wire), an infra red (IR) interface, a free space optical (laser) and a wireless interface. The external computing system **2940** utilizes at least one of the following protocols: IEEE 802.11, IEEE 802.15, IEEE 802.16, CDMA 2000, WCDMA, UMTS, GPRS, 2.5G, 3G, 4G, 5G, GSM.

The flat panel directional antennas are attached to one another at a defined angle. In **Fig. 29**, the six antennas are attached to one another side-by-side in an angle of 120 degrees. However, the defined angle in which the flat panel directional antennas are attached to one another can be changed in order to maximize efficiency of the antenna system. An adjustable varying of the angle between to adjacent antennas is performed within a predefined range. In one extreme case, all six flat panel directional antennas in **Fig. 29** can be attached to one another with

zero degree in the same plane, so that all six antennas will be radiating electromagnetic signals in the same direction covering the same region of three-dimensional space.

In another configuration, the six antennas are divided into two groups of three antennas each, wherein each of the three antennas are in the same plane and transmitting in the same direction covering the same region of three-dimensional space.

In **Fig. 29**, the six antennas are attached to one another side-by-side so that they can fold to occupy less space and be opened only for operation. The flat panel directional antennas are attached to one another at a defined angle that can be changed by mechanical means for changing the defined angles responsive to a control signal.

In **Fig. 30**, the four antennas are attached with arms **3030** in a fixed orientation to the support antenna structure **3000**. In this configuration each antenna **3021**, **3022**, **3023** and **3024**, can be directed independently in three-dimensional space, and their respective directions can be changed mechanically. The capability to vary the antenna orientations in three-dimensional space can be used for at least one of the following: to optimize three-dimensional space coverage, to optimize three-dimensional space antenna system gain. The re-orientation of the flat panel directional antennas is performed by moving at least one of: the arms **3030**, the antenna structure **3000**, the individual flat panel antenna sector **3021**, **3022**, **3023** or **3024**.

The antenna system in **Figs. 29-30** includes omni-directional antenna **2920** that is used to transmit in all directions. The omni-directional antenna **2920** is coupled to the antenna control system **2930**.

Fig. 31 is a schematic description of a vertical slice of cylindrical shape structure such that six such vertical slices with hexagonal arrangement are needed for covering 360°. This vertically stackable example provides for quadruple spatial vertical coverage. The flat panel directional antenna sectors that are arranged in a plurality of vertically stackable slices provides for greater vertical coverage with higher antenna gain. In the example of **Fig. 31**, there are four antenna sectors in each vertical slice, such that the main radiation lobe of each sector covers 30 degree vertically with combined vertical coverage of 120 degrees. The vertically stackable slices can be positioned as though mounted upon an outer surface of a cylindrically shaped object forming a hexagonal structure.

From the foregoing, it will be observed that numerous variations and modifications may be effected without departing from the spirit and scope of the invention. It is to be understood that no limitation with respect to the specific apparatus illustrated herein is intended or should be inferred. It is, of course, intended to cover by the appended claims all such modifications as fall
5 within the scope of the claims.
